

Seagrass Stories

Educator Guide · Ages 12-14 · 60 minutes

Driving question: What does it take to bring an underwater meadow back to life?

Learning intention: Explore how seagrass restoration works and use what you discover to help someone else understand it.

Learning outcomes

Understand how restoration supports the recovery of seagrass meadows.

Investigate how the game represents restoration through changes, timescales and evidence of recovery.

Create an experience that uses choices, consequences and change over time to communicate an idea about ocean restoration.

What you need

Internet-connected display and student devices where possible; access to the Seagrass Stories webpage and game; 6-10 Post-its per group; pens or markers; learner activity sheet.

Learning by doing

Learners encounter the subject, investigate it through play, make sense of the experience together and apply their understanding through creation. Facilitation focuses on curiosity, questions, connections and evidence of learning.

Stage	Learners do	Evidence of learning	Facilitator focus
Experience 15 min	Watch, notice relationships, meet Nada and form questions.	Learners identify features, relationships, surprises and questions.	Invite observation and curiosity. Surface different perspectives.
Investigate 15 min	Play the game through the lens of a scientist and examine change, timescale and recovery.	Learners explain what changes, what may take longer and what evidence could show recovery.	Ask for reasoning and evidence. Invite learners to test their assumptions.
Reflect & Discuss 15 min	Reflect individually, then share and compare thinking.	Learners articulate how their thinking has changed and identify new questions.	Help learners connect the videos, game and their own observations.
Create 15 min	Use 6-10 Post-its to design an experience that communicates an idea about restoration.	Learners make understanding visible through choices, consequences, habitat responses and change over time.	Ask: What happens because of what? Encourage clear causal relationships.

The 6-10 Post-it constraint

The constraint gives learners enough elements to explore relationships and consequences while keeping the system workable. Ask groups to connect the Post-its with arrows and explain the relationships they have created.

Science note

Restoration mats support transplanted seagrass shoots so they can stay in place, take root and grow. The game represents parts of the restoration process. Use the Investigate stage to explore changes, timescales and evidence of recovery. Complete final science review with the relevant OceanX content lead before wider release.

After the session

Capture observations that can improve the next iteration: where curiosity appeared, which connections learners made, what their creations revealed about understanding, and where facilitation or resources could be strengthened.
